+-----+			

An LLM, or Large Language Model, is a type of artificial intelligence designed to understand and generate human language. ChatGPT is an example of an application built around an LLM.

An LLM is trained on very large amounts of data, such as books, websites, articles, code, and other text.

During training, it learns statistical patterns in language, including how words and concepts relate to one another.

When you give an LLM a prompt, it processes the text and predicts what should come next.

It does this repeatedly, generating one token at a time.

A token can be a word, part of a word, punctuation, or another small piece of text.

Modern LLMs generally use an architecture called a transformer.

Transformers are particularly effective at understanding relationships between different parts of a piece of text.

This allows an LLM to maintain context and produce responses that appear to understand what you are asking.

LLMs can perform many different tasks because the same underlying language capabilities can be applied in different ways.

They can explain concepts, summarize documents, translate languages, generate code, answer questions, analyze information, and more.

However, an LLM does not necessarily know things in the same way a human does.

Its responses are generated from patterns learned during training and, depending on the system, information provided through tools or additional context.

This is why LLMs can sometimes produce confident but incorrect information, a problem commonly called hallucination.
